

After taking the quiz on learning styles as well as reading the article on learning styles I'm a little indecisive on my opinion of if learning styles actually affect the way that people learn. Before doing any previous research I disagree with the idea that learning styles are as important as some people think. I think that some methods can help certain people remember knowledge better than others but I think that it generally goes down to how much effort you put into the knowledge that you want to learn. I think that you get rewarded for how hard you work and that some people can interpret that as having a different learning style that can affect how quickly people learn.

When I took the learning style quiz it told me that I was a tactile and auditory learner which I find very interesting because my preferred form of studying and learning is either doing something myself and I generally find it very hard to learn things from listening to someone go over it. So having about half of this test be correct is very interesting because I think that it does have some merit in the fact that it can tell that I learn better from doing things myself. I think that the idea that a test could decide what it thinks your learning styles are is both a good thing and a bad thing because I think that it helps someone possibly understand where their basis is and what could help them learn better but I also think that it could be very inaccurate and lead someone astray. I don't think that a digital learning style test could ever replace just personal experience of trying to learn in different ways and seeing what works best for you.
